# CLASSIFICATION OF THE FOSSORIAL, PREDACEOUS AND PARASITIC WASPS, OR THE SUPERFAMILY VESPOIDEA.

BY WILLIAM H. ASHMEAD, A. M., ASSISTANT CURATOR, DIVISION OF INSECTS, U. S. NATIONAL MUSEUM.

(Paper No. 11.-Continued from Vol. XXXIV., p. 291.)

FAMILY XXXIV.—Sapygidæ.

The wasps belonging to this family, on account of the emarginate eyes in the females, and the abdomen being usually marked with yellow or white, closely resembles those in the families Myzinidæ and Scoliidæ, but may be easily distinguished by the great difference in the legs, the middle coxæ being approximate, the outer face of the tibiæ being smooth, unarmed, without tubercles or spines, while the tarsi are without strong spines or bristles, and unfitted for digging.

The antennæ, too, are different; they are inserted much farther apart, being nearer to the eye margin than to each other. The pronotum is broader, abruptly truncate anteriorly, with the front angles more acute, while the venation, at least in the front wings, is wholly different from the venation in the *Myzinidæ* and the *Scoliidæ*, the stigma being distinct, never small, the marginal cell larger, lanceolate, the basal nervure slightly arcuate, with the cells different. The males are easily known by the *unarmed* hypopygium.

In habits the species agree with those in the *Trigonalida*, being parasitic in the nests of wasps and bees.

## Table of Genera.

Antennæ at apex similar in both sexes, the last joint in the male not enclosed by the penultimate..... (1) Eusapyga, Cresson.

(Type E. rubripes, Cr.)

Antennæ similar in both sexes, filiform, tapering off at apex; mandibles broad, 3-dentate, the teeth blunt, equal; maxillary palpi 6-jointed, labial palpi 4-jointed......(2) Polochrum, Spinola. (Type P. repanda, Spinola.)

3. Third joint of the antennæ not longer than the fourth; second cubital cell narrowed above; antennæ in female clavate, in male subfiliform, the last joint more or less enclosed by the penultimate; mandibles 3-dentate, the teeth acute, the outer tooth a little the

longest .....(3) Sapyga, Latreille.
(Type Apis clavicornis, Fabr.)

Third joint of the antennae longer than the fourth; second cubital cell not much narrowed above; antennae in female subfili-

form.....(4) Sapygina, Costa. (Type Sapyga decemguttata, Jurine.)

## FAMILY XXXV .--- Myzinidæ.

This family is usually classified with the *Scoliidæ*. According to my views, it is quite distinct, although closely allied, and is easily separated by the difference in the shape of the eyes in the females, and by the totally different armature of the male genitalia.

The eyes in a female Myzinid are always entire, never emarginate within, as in the Scoliidæ. The males have the eyes emarginate or sinuate within, much as in the Scoliidæ, but are easily distinguished by difference in venation and by the armature of the genitalia, the tip of the abdomen always ending in a single upward curved aculeus.

In the Scoliidæ the abdomen in the males terminates in three straight spines.

The family is without doubt *parasitic*, but nothing seems to be known of the habits of the many species already described.

Many of our species are common in midsummer and early fall; they are conspicuous and easily observed, and some of our younger entomologists should make an effort toward unravelling their lifehistories

The genus *Menisus*, Du Buysson, I do not know; it may be Sapygid, but I am unable to place it from the description.

The species in our catalogues, under the genus Myzine, do not belong to it, but should be removed to the genus Plesia, Jurine.

#### Table of Genera.

Passilotiphia Cameron

3. Front wings with three cubital cells, rarely with two cubital cells . . 4.

Second cubital cell receiving both recurrent

Front wings with two cubital cells.

	(Type P. albomaculata, Cam.)
4.	Marginal cell not at all or only slightly separated from the costa;  three cubital cells, the second and third each receiving a recurrent nervure
	Marginal cell widely separated from the costa, nearly to the stigma, and directed forward into the disc of the wing, so as to occupy the place usually occupied by the third cubital cell.  Two cubital cells
5.	Three cubital cells
6.	Second cubital cell neither small nor petiolate
7.	Second cubital cell large, longer than wide, trapezoidal, receiving the recurrent nervure far beyond the middle; hind tarsi about twice as long as their tibiae; cubitus in hind wings originating behind the transverse median nervure; mandibles long, sickel-shaped, edentate
	Second cubital cell not so large, receiving the recurrent nervure at the middle; mandibles stout, curved, edentate. Dimorphoptera, Smith.)  (Type D. scoliiformis, Smith.)
8.	Cubitus in hind wings originating beyond the transverse median

nervure; hind tibiæ elongate, triangulate; last joint of hind tarsi not smaller than the fourth....Micromeria (Westwood) Saunders.

(Type Meria, Llugii, Westwood.)

	Cubitus in hind wings originating (?) before the transverse median nervure; hind tibie globose; last joint of hind tarsi very
	minute
9.	Wings glabrous, not hairy
	Wings hairy, strongly fimbriate.
	Apical lobes of front wings unequal; stigma and veins absent
	(Type K. victoriosa, Radoszk.)
10.	Apex of wings bilobed, the marginal cell wanting; one cubital and
	two discoidal cells; mandibles at apex bifid; hind tibial spur
	moderate, straight and acutePseudomeria, Saunders.  (Type P. graeca, Saund.)
	Apex of wings pointed; one or two discoidal cells; mandibles
	at apex simple, edentate; hind tibial spur very long, slender,
	acute (Africa)
	(Type Tiphia brevipennis, Lucas.)
11.	Front wings with <i>three</i> cubital cells
	Second cubital cell receiving both recurrent
	nervuresPoecilotiphia, Cameron.
I 2.	Marginal cell at apex not at all or only slightly separated from the
	costa; second cubital cell large, irregularly quadrangular, trapezoidal or pentagonal, longer than the third
	Marginal cell at apex widely separated from the costa; second
	cubital cell small, longly petiolate
13.	Marginal cell <i>shorter</i> , rounded or truncate at apex; second cubital cell long, in outline triangular
	Marginal cell long, its apex oblique and with a slight curve inwards
	near the costa; three cubital cells, the second cell large, the
	second and third each receiving a recurrent nervure, or the
	second recurrent is interstitial with the second transverse cubitus; cubitus in hind wings originating before the transverse median
	nervure
14.	Apex of marginal cell narrowly rounded; second cubital cell
	receiving the first recurrent nervure at or a little before the
	middle, the second recurrent nervure received by the third cubital cell before the middle
	con try and an analysis of the state of the

(Type M. diapherogamia, Sauss.)

#### Family XXXVI.—Scoliidæ.

This family is very closely allied to the *Myzinidæ*, but may be easily separated by having the eyes in the females distinctly *emarginate* within. The males also have emarginate eyes, but are more easily distinguishable by abdominal peculiarities, the tip ending in *three* straight spines, but never in a single upward curved aculeus as in the *Myzinidæ*.

The species are parasitic upon the larvæ of beetles belonging to the family *Scarabaeidæ*, and probably also upon other ground-inhabiting beetle larvæ.

Two subfamilies may be recognized:

# Subfamily I.—Scoliinæ.

In this subfamily the front wings have only a single complete recurrent nervure, which is received by the second cubital cell. The group is evidently an offshoot from the *Elidinæ*, which have two complete recurrent nervures.

#### Table of Genera.

r. Front wings with four discoidal cells, the third usually triangular, often petiolate
Front wings with three discoidal cells.
Two closed cubital cells Discolia, Saussure.
(Type Scolia apicicornis, Guér.)
Three closed cubital cells Scolia, Fabricius.
= Triscolia, Sauss.
= Triliacos, Sauss. (partim.)
(Type S. flavifrons, Fabr.)
2. Two cubital cells
(Type Compsomeris violacea, Lepels.)

Three cubital cells . . . . . . Liacos, Guérin. = Triliacos, Sauss. et Sich (partim.) (Type L. dimidiata, Guérin.)

#### SUBFAMILY II.-Elidinæ.

This subfamily is separated from the *Scoliinue* by having two recurrent nervures, and both being received by the second cubital cell. It is the older type of the two subfamilies, and is clearly shown by the more numerous cells in the front wings.

The present conception of the genus *Elis* appears to be wrong. *Elis*, as established by Fabricius, was a most composite group, and some of the species originally placed in it by Fabricius did not even belong to the same family.

Fabricius, when he established Elis, placed under it seven species, viz.: (1) E. sexcincta, (2) E. interrupta, (3) E. seniles, (4) E. 7-cincta, (5) E. cylindrica, (6) E. volvulus and (7) E. cochleata. Subsequently, some of these were placed in other genera, and the first species, Elis sexcincta, became the type of the genus Myzine, Latr. After going carefully over the literature, I find that the only species left to which the Fabrician name Elis may be applied is Elis (Scolia) 7-cincta. This must now be considered the type of the genus; it will throw out the generic names, Colpa, Lep.; Compsomeris, Lep., and Dielis, Sauss., and what we have been calling Elis becomes Trielis, Saussure.

#### Table of Genera.
